

ABSTRACT

A method for supervising a network connection employing an electronic apparatus employing in turn an operating system of a non-event driven system. The electronic apparatus includes a connector jack for a local area network (LAN), an access controller for detecting that a LAN cable has been connected to or disconnected from the connector jack, and a micro-computer. A detection output of the access controller is supplied as an interrupt signal to the micro-computer. Upon detection of the interrupt signal, the micro-computer carries out the processing for connection/disconnection of the LAN cable.
